• Informally, the definite integral is the area under a graph (p5-11, §5.2 in textbook).

• The definite integral is defined to be a limit of something called a Riemann sum, and is painfully hard to compute by hand (p12, §5.3-5.4 in textbook).

• The Fundamental Theorem of Calculus (FTC) says that a definite integral of f can be calculated using its antiderivative (i.e. by finding a function F with $f=\frac{dF}{dx}$). This is much easier than using the definition (p21-30, §5.5 in textbook).

Many interesting geometric quantities are limits of Riemann sums. By rewriting these as multiple integrals and using FTC, we can evaluate some of them using antiderivatives (week 5 notes, $\S14$ in textbook).

functions have elementary antiderivates. (An elementary function is a function that is functions is something that we do not have a name for. So, in almost all applications, "built out of" $x^n, e^x, \ln x, \sin x, \cos x$.) In other words, the integral of most familiar This story is extremely important because only a tiny proportion of elementary functions are integrated numerically using Riemann sums.

Semester 2 2017, Week 3, Page 1 of 36

Integration is about adding many things together, so it's useful to have some notation for sums. **Definition**: If m and n are integers with $m \leq n$, and f is a function defined at $m, m+1, \ldots, n$, then

$$\sum_{i=1}^{n} f(i) = f(m) + f(m+1) + \dots + f(n).$$

In this formula, i is the index of $\mathit{summation}$, m is the lower limit and n is the upper limit . Note that the index of $\mathit{summation}$ i is a "dummy variable" and can be changed without changing the value of the sum, i.e. $\sum_{i=m} f(i) = \sum_{j=m} f(j)$.

Examples:

$$\sum_{i=2}^{5} i^2 = 2^2 + 3^2 + 4^2 + 5^2. \qquad \sum_{j=5}^{n} jx^j = 5x^5 + 6x^6 + \dots + (n-1)x^{n-1} + nx^n.$$
 HKBU Math 2205 Multivariate Calculus
$$\sum_{j=5}^{5} i^2 = 2^2 + 3^2 + 4^2 + 5^2. \qquad \sum_{j=5}^{n} jx^j = 5x^5 + 6x^6 + \dots + (n-1)x^{n-1} + nx^n.$$
 Semester 2 2017, Week 3, Page 2 of 38

Semester 2 2017, Week 3, Page 2 of 36

Definition: If m and n are integers with $m \le n$, and f is a function defined at

$$\sum_{i=m}^{n} f(i) = f(m) + f(m+1) + \dots + f(n).$$

The function f(i) can itself be a sum (with a different index of summation) - in the example below, $f(i) = \sum_{j=2}^4 \frac{x^i}{i+j}.$

Example:
$$\sum_{i=3}^{4} \sum_{j=2}^{x^i} \frac{x^i}{i+j} = \sum_{i=3}^{4} \frac{x^i}{i+2} + \frac{x^i}{i+3} + \frac{x^i}{i+4}$$

$$= \frac{x^3}{3+2} + \frac{x^3}{3+3} + \frac{x^3}{3+4} + \frac{x^4}{4+2} + \frac{x^4}{4+3} + \frac{x^4}{4+4}.$$

$$i=3 \qquad i=3 \qquad i=3 \qquad i=4 \qquad i=4$$

$$j=2 \qquad j=3 \qquad j=4 \qquad j=4$$

$$j=2 \qquad j=3 \qquad j=4 \qquad j=4$$
 Semester 2 2017, Week 3, Page 3 of 36

Some properties of sums:

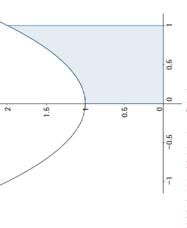

• If
$$A$$
 and B are constants, then $\sum_{i=m}^n (Af(i)+Bg(i))=A\sum_{i=m}^n f(i)+B\sum_{i=m}^n g(i);$

Example:
$$\sum_{i=1}^n \frac{i^2+i}{3} = \frac{1}{3} \sum_{i=1}^n i^2 + \frac{1}{3} \sum_{i=1}^n i \text{ and } \sum_{i=1}^n \frac{i^2+i}{n} = \frac{1}{n} \sum_{i=1}^n i^2 + \frac{1}{n} \sum_{i=1}^n i$$

•
$$\sum_{i=1}^{n} 1 = \underbrace{1 + i = 2}_{n \text{ times}}$$
 i = n ... $i = n$.

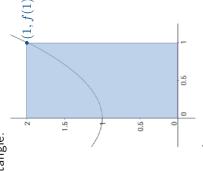

Example: Combining the two properties, $\sum_{i=1}^n \frac{1}{n} = \frac{1}{n} \sum_{i=1}^n 1 = \frac{1}{n} = 1$.

region bounded by the lines $x=0,\,x=1,$ y=0 and the graph of $f(x)=x^2+1.$ Suppose we want to find the area of the

HKBU Math 2205 Multivariate Calculus

approximate the region by this A first step might be to rectangle:

Approximate area

Semester 2 2017, Week 3, Page 5 of 36 = width \times height =1f(1)=2.

HKBU Math 2205 Multivariate Calculus

We obtain a better approximation by

$$\left(\frac{1}{2}\right) + \frac{1}{2}f(1) = \frac{1}{2} \frac{5}{4} + \frac{1}{2}2 = 1.625.$$

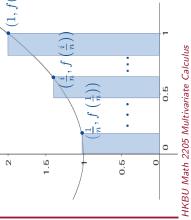

$$f(x)$$

$$+1$$

$$0.6$$

Semester 2 2017, Week 3, Page 6 of 36

$$\frac{1}{n}f\left(\frac{1}{n}\right) + \frac{1}{n}f\left(\frac{2}{n}\right) + \dots + \frac{1}{n}f\left(\frac{i}{n}\right) + \dots + \frac{1}{n}f(1) = \sum_{i=1}^{n} \frac{1}{n}f\left(\frac{i}{n}\right),$$

the properties of sums (p4) because of

Remembering $f(x) = x^2 + 1$, this approximate area is: $\sum_{i=1}^n \frac{1}{n} \left(\left(\frac{i}{n}\right)^2 + 1 \right) = \sum_{i=1}^n \left(\frac{i^2}{n^3} + \frac{1}{n}\right)$

 $= \sum_{i=1}^{n} \frac{i^2}{n^3} + \sum_{i=1}^{n} \frac{1}{n}$ $= \frac{1}{n^3} \left(\sum_{i=1}^{n} i^2 \right) + 1.$

 $\frac{1}{4}f\left(\frac{1}{4}\right) + \frac{1}{4}f\left(\frac{2}{4}\right) + \frac{1}{4}f\left(\frac{3}{4}\right) + \frac{1}{4}f\left(\frac{3}{4}\right) + \frac{1}{4}f(1)$ = 1.46875. We have an even better approximation using two rectangles:

Approximate area $=\frac{1}{2}f\left(\frac{1}{2}\right)+\frac{1}{2}f(1)=\frac{1}{2}\frac{5}{4}+\frac{1}{2}2=1.625.$

The approximate area using \boldsymbol{n} rectangles is

because the ith rectangle has width $\frac{1}{n}$ and height $f\left(\frac{i}{n}\right)$.

Semester 2 2017, Week 3, Page 7 of 36

From the last page: the approximate area using n rectangles is $\left(\frac{1}{n^3}\sum_{i=1}^n i^2\right)+1.$

Fact:
$$\sum_{i=1}^{n} i^2 = \frac{n(n+1)(2n+1)}{6}$$
.

(This formula is unimportant for the rest of the class so we will not prove it, see \$5.1 Theorem 1c in textbook.)

So the approximate area using
$$n$$
 rectangles is
$$\frac{1}{n^3}\frac{n(n+1)(2n+1)}{6}+1=\frac{4}{3}+\frac{1}{2n}+\frac{1}{6n^2}.$$

Because our approximation becomes more and more accurate as we use more and more rectangles, the true area must be the limit

$$\lim_{n \to \infty} \frac{4}{3} + \frac{1}{2n} + \frac{1}{6n^2} = \frac{4}{3}$$

(This type of computation is important theoretically, but we will rarely compute like

l this.) HKBU Math 2205 Multivariate Calculus

In general, to find the area under the graph of a continuous, positive function $f:[a,b] \to \mathbb{R}$: 1. Divide [a,b] into n subintervals by choosing x_i

satisfying $a=x_0< x_1< \cdots < x_n=b$. Let

Consider the ith approximating rectangle: its width is

So the total area of the approximating rectangles is

 $\sum_{i=1}^n \Delta x_i f(x_i).$ This type of sum is a *Riemann sum*

If all Δx_i are equal, then the limit $\lim_{n \to \infty} \sum \Delta x_i f(x_i)$

(If the Δx_i are not all equal will exist and is the area under the graph. then we have to choose x_i are carefully.)

Semester 2 2017, Week 3, Page 9 of 36

HKBU Math 2205 Multivariate Calculus

Example: Consider the function $f:[0,2] \to \mathbb{R}$ given by $f(x) = 2 + \cos x$.

- a. Use a Riemann sum with 3 subintervals of equal
- width to approximate the area under the graph of f.
- b. Express the exact area under the graph of \boldsymbol{f} as a limit of a Riemann sum.

a. To divide [0,2] into 3 subintervals of equal width, take $\Delta x_i = \frac{2}{3}$, so

$$x_0=a=0, \ x_1=rac{2}{3}, \ x_2=rac{4}{3}, \ x_3=b=2.$$
 So the Riemann sum is
$$\sum_{i=1}^3 \Delta x_i f(x_i)=rac{2}{3}\left(2+\cosrac{2}{3}
ight)+rac{2}{3}\left(2+\cosrac{4}{3}
ight)+rac{2}{3}\left(2+\cos2
ight).$$

b. To divide [0,2] into n subintervals of equal width, take $\Delta x_i = \frac{2}{n}$, so $x_i = \frac{2}{n}i$.

So the area under the graph is $\lim_{n\to\infty}\sum_{i=1}^n\Delta x_if(x_i)=\lim_{n\to\infty}\sum_{j=1}^n\frac2n\left(2+\cos\frac{2i}n\right).$

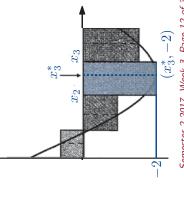

HKBU Math 2205 Multivariate Calculus

§5.3-5.4: The Definite Integral

For functions $f:[a,b] o \mathbb{R}$ taking both positive and negative values, the Riemann sum $\sum_{i=1}^{\infty} \Delta x_i f(x_i^*)$ is still defined. But what does this mean when f is negative?

To answer this, suppose $f(\boldsymbol{x}_3^*) = -2$ in the Then the 3rd term in the Riemann sum is diagrammed example.

diagram is 2. So its area is $\Delta x_3 2$, the negative The height of the 3rd (blue) rectangle in the of the 3rd term in the Riemann sum.

Semester 2 2017, Week 3, Page 12 of 36

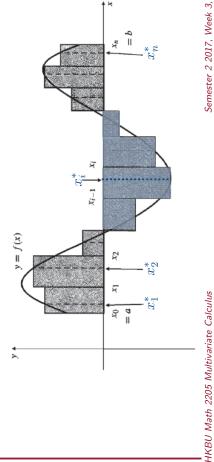

Let $f:[a,b] \to \mathbb{R}$ be a continuous, positive function, and $a=x_0 < x_1 < \cdots < x_n = b$ a division of [a,b] into n subintervals of equal width Δx_i . We saw (p9) that the area height of the approximating is that, when n is sufficiently big, the interval $\left[x_{i-1},x_i
ight]$ more general Riemann sum $\lim_{n \to \infty} \sum \Delta x_i f(x_i^*)$, where \boldsymbol{x}_i^* is any point in the interval $[x_{i-1}, x_i]$. The intuition Actually, we can calculate the area as the limit of the is very small, so f does not change much within the interval, and which value of f we use as the rectangles will not make under the graph of f is $\lim_{n\to\infty}\sum\Delta x_i f(x_i)$.

HKBU Math 2205 Multivariate Calculus Semester 2 2017, Week 3, Page 11 of 36

HKBU Math 2205 Multivariate Calculus

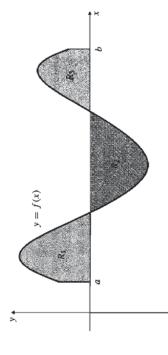

much difference.

above the x-axis and below the graph, minus the area of the blue rectangles, which are below the x-axis and above the graph

Semester 2 2017, Week 3, Page 13 of 36

So the limit $\lim_{n o\infty}\sum_{j\to\infty}^n\Delta x_if(x_i^*)$ is the signed area: the total area below the graph and above the x-axis, minus the total area above the graph and below the x-axis.

The signed area is an interesting quantity: for example, if f is velocity, then the signed area is the change in position. So let's define this to be the integral.

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 14 of 36

Definition: Let $a=x_0< x_1< \cdots < x_n=b$ be a division of [a,b] into n subintervals of equal width Δx_i , and let x_i^* be a point in $[x_{i-1},x_i]$. A function

 $f:[a,b] \to \mathbb{R}$ is integrable if $\lim_{n \to \infty} \sum \Delta x_i f(x_i^*)$ exists and is independent of the

choice of x_i^* in $[x_{i-1},x_i]$. The value of this limit is the *integral of* f on [a,b] (or the integral of f from a to b):

$$\int_{a}^{b} f(x) dx = \lim_{n \to \infty} \sum_{i=1}^{n} \Delta x_{i} f(x_{i}^{*}).$$

It is hard to use this definition to prove that a function is integrable. Luckily, we have the following theorem:

Theorem 2: Continuous functions are integrable: If f is (piecewise)

continuous on [a,b] , then f is integrable on $\overline{[a,b]}$

Terminology of the various parts of the integral symbol $\int f(x) \, dx$:

- ullet is the *integral sign* it is a long S for "sum".
- a is the lower limit of integration and b is the upper limit of integration.
 - ullet is the *integrand*, the function that is being integrated.
- dx tells us that the variable of integration is x. The variable of integration is a dummy variable like the index of summation (p2), we can change it without changing the value of the definite integral, e.g. $\int_a^b f(x) dx = \int_a^b f(t) dt$.

Important:

- The definite integral is a number, not a function.
- integral or antiderivative. It is a function of x, whose derivative is f. At the \bullet The symbol $\int f(x)\,dx$, without any limits of integration, is the $\mathit{indefinite}$ moment we do not know that it is related to the definite integral.

Semester 2 2017, Week 3, Page 15 of 36

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 17 of 36

HKBU Math 2205 Multivariate Calculus

limits of the integral without worrying about which limit is bigger (e.g. p21). The convention which makes all our later theorems work is It will be useful to define $\int_{-\infty}^{\infty} f(x) \, dx$ when a>b, so we can put variables in the

$$\int_{a}^{b} f(x) dx = -\int_{b}^{a} f(x) dx,$$

i.e. reversing the limits of integration changes the sign of the integral

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 18 of 36

Important properties of the definite integral (the labelling follows $\S 5.4$ Theorem 3 in textbook):

- $\int_a^b Af(x) + Bg(x)\,dx = A\int_a^v f(x)\,dx + B\int_a^v g(x)\,dx. \text{ This comes from the corresponding property of Riemann sums (p4).}$ d. An integral depends additively on the interval of integration: $\int_a^b f(x)\,dx + \int_b^c f(x)\,dx = \int_a^c f(x)\,dx.$ c. An integral depends linearly on the integrand: if A and B are constants, then

$$\int_{a}^{c} f(x) dx$$
.

The from thinking a, b, c are in a, b, c are in d

For the case a < b < c, this is believable from thinking another order, we need to use identity/definition from about integrals as signed areas. When a,b,c are in

We can deduce from d. that the previous page.

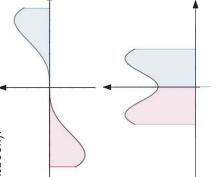

a.
$$\int_a^a f(x) \, dx = 0.$$

HKBU Math 2205 Multivariate Calculus

integrals (the labelling follows §5.4 Theorem 3 in textbook): $\text{g. If } f \text{ is an odd function } \big(f(-x) = -f(x)\big),$ then $\int_{-a} f(x) dx = 0$.

The following two properties shows how to use symmetry to simplify some

h. If f is an even function $\big(f(-x)=f(x)\big),$ then $\int_{-a}^a f(x)\,dx=2\int_0^a f(x)\,dx.$

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 19 of 36

Semester 2 2017, Week 3, Page 20 of 36

§5.5: The Fundamental Theorem of Calculus

This important theorem is in two parts:

Theorem 5: Fundamental Theorem of Calculus (FTC): Let $f:[a,b] o \mathbb{R}$ be a continuous function. FTC1. The cumulative area function $F:[a,b] o \mathbb{R}$ defined by $F(x)=\int^{\mathbb{T}}f(t)\,dt$

is differentiable, and is an antiderivative of f, i.e. F'(x)=f(x). FTC2. If $G:[a,b]\to \mathbb{R}$ is any antiderivative of f (i.e. G'(x)=f(x)), then

$$\int_{a}^{b} f(x) \, dx = G(b) - G(a).$$

FTC1 explains how to differentiate a cumulative area function, and is mainly for theoretical use.

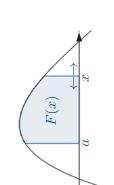

FTC2 explains how to compute a definite integral if you can find the antiderivative of the integrand - this will be very useful to us.

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 21 of 36

FTC1 will be "obvious" if we understand the cumulative area function

$$F(x) = \int f(t) dt$$

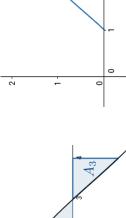

First note that such a function is defined whether $x \geq a$ or x < a, because of our definition / identity (p18) that reversing the limits of an integral changes its sign.

Despite the slightly scary formula, cumulative area functions are very natural: for example, if f(t) is the rate that a company is earning money at time t, then F(x) is the total money earned from time a to time x. (Cumulative area functions are also very important in probability.)

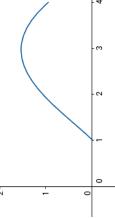

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 22 of 36

Suppose this is the graph of

Let's sketch its cumulative area function $F(x) = \int_1^x f(t) dt.$

- $F(1)=\int_{\mathbb{T}}^{1}f(t)\,dt=0$ by the properties of definite integrals.
- $A_2 < A_1$ so the increase in F between 2 and 3 is less than it was between 1 and 2 • $F(2)=\int_1^2 f(t)\,dt=A_1$, which is a positive number. • $F(3)=\int_1^3 f(t)\,dt=A_1+A_2$. Since $A_2>0$, we must have F(3)>F(2), but
 - $F(4) = \int_1^4 f(t) dt = A_1 + A_2 A_3$, so F(4) < F(3). HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 23 of 36

Observe that we were sketching $F(\boldsymbol{x})$ by considering the increase or decrease of ${\cal F}$, i.e. the derivative of ${\cal F}$. This derivative is:

or decrease of
$$F$$
 , i.e. the derivative of F . Inis derivative is:
$$F'(x) = \lim_{h \to 0} \frac{F(x+h) - F(x)}{h} \text{ definition of derivative}$$

$$\frac{1}{0} \left[\int_{a}^{x+h} f(t) \, dt - \int_{a}^{x} f(t) \, dt \right]$$
 definition of $F \mid \int a = x - x + y - y = 0$ additive dependence
$$\lim_{x \to \infty} \frac{1}{x} \left[\left(\int_{a}^{x} f(t) \, dt + \int_{a}^{x+h} f(t) \, dt \right) - \int_{a}^{x} f(t) \, dt \right]$$
 the domain of

$$= \lim_{h \to 0} \frac{1}{h} \left[\left(\int_a^x f(t) \, dt + \int_x^{x+h} f(t) \, dt \right) - \int_a^x f(t) \, dt \right]$$
 additive dependence on
$$= \lim_{h \to 0} \frac{1}{h} \int_a^{x+h} f(t) \, dt.$$

By the Mean Value Theorem for Integrals (later, §5.4), there is a number $c\in[x,x+h]$ such that $\int_x^{x+h}f(t)\,dt=hf(c)$. So

number
$$c\in [x,x+h]$$
 such that $\int_x \ f(t)\,dt=hf(c).$ $F'(x)=\lim_{h\to 0} \frac{1}{h}hf(c)=\lim_{h\to 0} f(c)=f(x).$ HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 24 of 36

The previous page proved FTC1: $F(x) = \int_a^x f(t) \, dt$ is an antiderivative of f.

Now we use FTC1 to prove FTC2: $\int_a^b f(t) \, dt = G(b) - G(a)$ for any antiderivative G of f.

Because G and F are both antiderivatives of f, we must have F(x)=G(x)+C for some constant C. So f^b

$$\int_{a}^{b} f(t) dt = F(b)$$

$$\ \, {\rm definition} \,\, {\rm of} \,\, F$$

because
$$F(a) = \int_{a}^{a} f(t) dt = 0$$

= F(b) - F(a)

$$= (G(b) + C) - (G(a) + C) \text{ using } F(x) = G(x) + C$$

$$= G(b) - G(a).$$

$$=G(b)-G(a).$$

Semester 2 2017, Week 3, Page 26 of 36

Redo Example: (p5-8) Compute $\int_0^1 x^2 + 1 \, dx$ using FTC2.

To simplify the notation when using FTC2, we write $F(x)|_a^b$ to mean F(b)-F(a). (The alternative notation $[F(x)]_a^b$ will also be accepted.) Recall that the symbol $\int f(x)\,dx$ means the general antiderivative of f. So FTC2 says $\int_a^b f(x)\,dx = \left(\int f(x)\,dx\right)\Big|_a^b$.

ays
$$\int_{a}^{b} f(x) dx = \left(\int f(x) dx \right)$$

Redo Example: (Q1 ex. sheet #5) Compute $\int_{-3}^{1} 2x \, dx$ using FTC2.

HKBU Math 2205 Multivariate Calculus

Redo Example: (p10) Compute $\int_0^2 2 + \cos x \, dx$ using FTC2.

$$\int x^r \, dx = \frac{x^{r+1}}{r+1} + C \text{ if } r \neq -1.$$

$$\int \sin x \, dx = -\cos x + C.$$

$$\cos x \, dx = \sin x + C.$$

$$\int e^x dx = e^x + C.$$

$$\int \frac{1}{-} dx = \ln|x| + C.$$

$$\int \frac{1}{x} \, dx = \ln|x| + C.$$

These can be proved by differentiating the right hand side, e.g. for the last line: if x>0, then $\ln |x|=\ln x$, and $\frac{d}{dx}\ln x=\frac{1}{x}$

 $\text{if } x < 0, \text{ then } \ln|x| = \ln(-x), \text{ and } \frac{d}{dx} \ln(-x) = \frac{1}{-x} (-1) = \frac{1}{x}.$

HKBU Math 2205 Multivariate Calculus

Some other useful antiderivatives that will be provided to you in exams:

$$\int \sec^2 x \, dx = \tan x + C,$$

$$\int \sec x \tan x \, dx = \sec x + C,$$

$$\int \csc^2 x \, dx = -\cot x + C,$$
$$\int \csc x \cot x \, dx = -\csc x + C,$$

$$\int \frac{1}{\sqrt{1 - x^2}} \, dx = \sin^{-1} x + C,$$

$$\int \frac{1}{1+x^2} \, dx = \tan^{-1} x + C.$$

the last two use implicit differentiation (see $\S 3.5$ of textbook). These can be proved by differentiating the right hand sides: the first four use the quotient rule (see §3.2 of textbook)

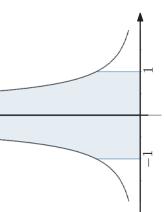

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 30 of 36

Warning: FTC2 only works for continuous integrands. For example, it cannot be applied to $rac{1}{x^2}$ on an interval containing 0, where the function is not defined.

$$\int_{-1}^1 \frac{1}{x^2} \, dx \neq \left(\frac{-1}{x}\right)\Big|_{-1}^1 = -2 \text{ we will see (§6.5) that the associated area is in fact infinite.}$$

sometimes have finite area - we will explore this Integrals like these, on an interval containing points where the integrand is not defined, are called improper integrals. These regions do

Now we look at a small generalisation of FTC2 that works for functions whose only discontinuities are a finite number of "finite jumps"

of the domain $a=c_0< c_1< \cdots < c_n=b$ such that f is continuous on each open **Definition**: A function $f:[a,b] \to \mathbb{R}$ is *piecewise continuous* if there is a division subinterval (c_{i-1},c_i) and $\lim_{x \to c_{i-1}^+} f(x)$ and $\lim_{x \to c_i^-} f(x)$ exist.

Example: The function $f:[1,5] \to \mathbb{R}$, given by

$$f(x) = \begin{cases} \frac{1}{x} & \text{if } 1 \le x < 2\\ \frac{x}{2} & \text{if } 2 \le x < 4\\ 1 & \text{if } x = 4\\ -3x + 14 & \text{if } 4 < x \le 5 \end{cases}$$
 is piecewise continuous.

Semester 2 2017, Week 3, Page 31 of 36

HKBU Math 2205 Multivariate Calculus

Informally, a piecewise continuous function is a function whose only discontinuities are a finite number of "finite jumps"

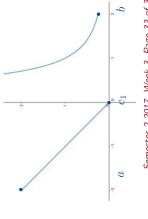

of the domain $a=c_0< c_1< \cdots < c_n=b$ such that f is continuous on each open **Definition**: A function $f:[a,b] \to \mathbb{R}$ is *piecewise continuous* if there is a division subinterval (c_{i-1},c_i) and $\lim_{x \to c_i^+} f(x)$ and $\lim_{x \to c_i^-} f(x)$ exist.

Non-Example: The function $f:[-2,2] \to \mathbb{R}$, given by

$$f(x) = \begin{cases} -x & \text{if } -2 \le x \ge 0\\ \frac{1}{x} & \text{if } 0 < x \ge 2. \end{cases}$$

 $\lim_{x\to c_1^+}f(x)=\lim_{x\to 0^+}\frac{1}{x}$ is infinite ("the is not piecewise continuous, because jump at $c_1 = 0$ is not finite").

HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 33 of 36

HKBU Math 2205 Multivariate Calculus

Our theorem (p15) says that piecewise continuous functions are integrable. Here's an example of how to calculate such integrals:

Example: Compute $\int_{1}^{\infty} f(x) dx$, where f is given by

$$f(x) = \begin{cases} \frac{x}{2} & \text{if } 2 \le x < 4 \\ 1 & \text{if } x = 4 \\ -3x + 14 & \text{if } 4 < x \le 5. \end{cases}$$

Semester 2 2017, Week 3, Page 34 of 36

How do we apply the method of the previous example to the general case, and

First, we use the property that the integral is additive on the domain of integration: $\int_{a}^{b} f(x) \, dx = \int_{c_{0}}^{c_{1}} f(x) \, dx + \dots + \int_{c_{n-1}}^{c_{n}} f(x) \, dx.$

Now define the continuous extension of f on each subinterval $\left[c_{i-1},c_{i}
ight]$:

$$f_i(x) = \begin{cases} \lim_{x \to c_{i-1}^+} f(x) & \text{if} & x = c_{i-1} \\ f(x) & \text{if} & x = c_i \end{cases} \qquad \text{(In practice, this usually means we apply the formula for } f(x) & \text{if } & x = c_i \\ \lim_{x \to c_i^-} f(x) & \text{if } & x = c_i \end{cases}$$

On each subinterval $\left[c_{i-1},c_{i}
ight]$, the extension f_{i} agrees with the original function f(which is possible since the integral does not depend on x_i^st), the Riemann sums except at the endpoints. So, as long as we don't use the endpoints as our x_i^st

for f_i and f are the same. So $\int_a^{} f(x) \, dx = \int_{c_0}^{^{-1}} f_1(x) \, dx + \cdots + \int_{c_{n-1}}^{^{-n}} f_n(x) \, dx$, and the f_i are continuous so FTC2 applies. HKBU Math 2205 Multivariate Calculus

Semester 2 2017, Week 3, Page 35 of 36

This techinque also works for continuous functions defined by different formulae on different subintervals, e.g. functions involving absolute values: recall

$$|g(x)| = \begin{cases} g(x) & \text{if } g(x) \ge 0 \\ -g(x) & \text{if } g(x) < 0. \end{cases}$$

Example: Compute $\int_{-3}^{\pi} |x+1| + |x-1| dx$.
